Google Chrome  
information access  
library information  
science  
research

The World Wide Web has stimulated social and technological transformations that are arguably comparable to those from the invention of the printing press. Both inventions have triggered similar reactions Scholars of that historical era were worried about keeping up with the rapid publication of books yet were also intrigued by growing information access. Today's overabundance of digital information AS EXEMPLIFIED BY OUR EMAIL INBOXES NEWS FEEDS AND WEB SEARCH RESULTS can be viewed similarly as both overwhelming information overload ARGUABLY CAN BE MENTIOND AS DATA POLLUTION and fascinating information access. This issue is triggering research across a wide variety of fields such as cognitive science psychology library information science humanComputer interaction and information visualization. But a lot of mentioned feilds are beyond the scope of this paper and my attention. Thereupon the information and interaction design are mainly focused.

Relevance levels

The Web arguably the most significant information space today is undergoing considerable transformations that enable entirely new ways for information seeking. In particular developments around webBased semantics graphics and interaction allow new ways for exploring information. More structured data are embedded into existing web pages and even entire information spaces such as the Wikipedia are exposed as semantic information spaces. The more powerful and semantic Information Retrieval and analyzer tools become to be. But there are always some concerns around using these powerful tools which make a part of online users to not employ them need to be expended. Beside that particularly when you start to make an research about an topic you actually start a journey. There is slightly a different between a search behavior and a research need to be expended. Here is where my proposal can take place; how to make our online research procedure more efficient.

 an ultimate content source which is web ..  
 arguably the most significant information space  
 ... In order to gain a better understanding  
 of browsing the web .. as new antitype of  
 information seeking .. I needed to slice up  
 this massive information source to an small  
 peace. By chosing my WebBrowser History ..  
 in this case: Chrome .. as an source for the  
 content could have an high relative sample.  
 Analyzing and clustreing all the information of  
 my brwoser history trigerd a new question How  
 relevant do we surf WWW? So far answering all  
 the questions is out of this research scope.  
 But the latest questions will couse some inner  
 questions which are listed as bellow

#### HOW RELEVANT DO WE SURF WWW?

The information retrieval community has  
 emphasized the use of test collections and  
 benchmark tasks to measure topical relevance  
 starting with the Cranfield Experiments of the  
 early s and culminating in the TREC evaluations  
 that continue to this day as the main  
 evaluation framework for information retrieval  
 research.

Research

In order to evaluate how well an information  
 retrieval system retrieved topically relevant  
 results the relevance of retrieved results  
 must be quantified. In Cranfield-style  
 evaluations this typically involves assigning  
 a relevance level to each retrieved result  
 a process known as relevance assessment.  
 Relevance levels can be binary (indicating a

result is relevant or that it is not relevant  
 .. or graded (indicating results have a  
 varying degree of match between the topic  
 of the result and the information need ...  
 Once relevance levels have been assigned to  
 the retrieved results information retrieval  
 performance measures can be used to assess the  
 quality of a retrieval system's output.

In contrast to this focus solely on topical  
 relevance the information science community  
 has emphasized user studies that consider user  
 relevance. These studies often focus on aspects  
 of human-computer interaction (see also human-  
 computer information retrieval ...

Problems  
 Mental Models  
 Navigation

#### WHAT IS RELEVANT SURFING?

An information retrieval process begins when a  
 user enters a query into the system. Queries  
 are formal statements of information needs  
 for example search strings in web search  
 engines. In information retrieval a query does  
 not uniquely identify a single object in the  
 collection. Instead several objects may match  
 the query perhaps with different degrees of  
 relevancy.

Queries  
 application

An object is an entity that is represented  
 by information in a database. User queries  
 are matched against the database information.  
 Depending on the application the data objects  
 may be for example text documents  
 images audio mind maps or videos.

Often the documents themselves are not kept or stored directly in the IR system but are instead represented in the system by document surrogates or metadata.

Most IR systems compute a numeric score on how well each object in the database matches the query and rank the objects according to this value. The top ranking objects are then shown to the user. The process may then be iterated if the user wishes to refine the query.

mind maps  
database

#### WHAT ARE THE ELEMENTS AND VARIABLES TO QUALIFY THE WEB BROWSING?

In linguistics semantic analysis is the process of relating syntactic structures from the levels of phrases clauses sentences and paragraphs to the level of the writing as a whole to their language-independent meanings. It also involves removing features specific to particular linguistic and cultural contexts to the extent that such a project is possible. The elements of idiom and figurative speech being cultural are often also converted into relatively invariant meanings in semantic analysis.

Google Chrome  
library information  
research

An object is an entity that is represented by information in a database. User queries are matched against the database information. Depending on the application the data objects may be for example text documents images audio mind maps or videos. Often the documents themselves are not kept

or stored directly in the IR system but are instead represented in the system by document surrogates or metadata.

Most IR systems compute a numeric score on how well each object in the database matches the query and rank the objects according to this value. The top ranking objects are then shown to the user. The process may then be iterated if the user wishes to refine the query.

#### HOW EFFICIENT DO WE SURF WWW?

Other research also stresses the fact that the internet addiction disorder is not a unidimensional but a multidimensional construct. Various facets of internet use must be differentiated because of their differential predictors mechanisms and consequences. Online activities which if done in person would normally be considered troublesome such as compulsive gambling or shopping are sometimes called net compulsions. Mass media is defined as the channels of communication in modern societies. The television radio and print were means of mass media which were commonly around the s. The internet in simple terms is a network of interlinked computer called the World Wide Web which is accessible to the general public. The internet has benefits much of advantages than more less of disadvantage.

screen. It also provide a well proper aspect of entertainment as a matter of fact every thing about this earth is made available by visiting the internet. On the contrary the internet disadvantages is less beneficiary to the society than it advantages. Nevertheless it can be said that the negative the internet weight more on the people in our modern society.

#### WHAT IS EFFICIENT SURFING?

The information retrieval community has emphasized the use of test collections and benchmark tasks to measure topical relevance starting with the Cranfield Experiments of the early s and culminating in the TREC evaluations that continue to this day as the main evaluation framework for information retrieval research.

In order to evaluate how well an information retrieval system retrieved topically relevant results the relevance of retrieved results must be quantified. In Cranfield-style evaluations this typically involves assigning a relevance level to each retrieved result a process known as relevance assessment. Relevance levels can be binary (indicating a result is relevant or that it is not relevant .. or graded (indicating results have a varying degree of match between the topic of the result and the information need ... Once relevance levels have been assigned to the retrieved results information retrieval performance measures can be used to assess the quality of a retrieval system's output. this database

typically involves assigning a relevance level to each retrieved result a process known as relevance assessment.

#### LESS POLLUTED INFORMATION EQUALS MORE EFFICIENT NAVIGATION?

A textbook formulation is “People are part of the system. The design should match the user’s experience expectations and mental models.” What is least surprising may however depend on the expected audience e.g. end users programmers or system administrators.

Problems

In more practical terms the principle aims to exploit users’ pre-existing knowledge as a way to minimize the learning curve for instance by designing interfaces borrowing heavily from “functionally similar or analogous programs with which your users are likely to be familiar.” User expectations in this respect may be closely related to a particular computing platform or tradition. For example Unix command line programs are expected to follow certain conventions with respect to switches and widgets of Microsoft Windows programs are also expected to follow certain conventions with respect to key bindings. In more abstract settings like an API the expectation that function or method names intuitively match their behavior is another example. This practice also involves the application of sensible defaults.

#### WEB APIS

API an abbreviation of application program interface is a set of routines protocols and tools for building software applications. The API specifies how software components should interact and are used when programming graphical user interface (GUI .. components.

Mind maps  
database

#### WHAT DO THESE TOOLS DO?

A web search engine is a software system that is designed to search for information on the World Wide Web. The search results are generally presented in a line of results often referred to as search engine results pages (SERPs) ... The information may be a mix of web pages, images, and other types of files. Some search engines also mine data available in databases or open directories. Unlike web directories, which are maintained only by human editors, search engines also maintain real-time information by running an algorithm on a web crawler.

performance measures  
Relevancy

#### WHAT ARE THE ADVANTAGE AND DISADVANTAGE OF THESE TOOLS?

In June, Matthew Gray, then at MIT, produced what was probably the first web robot, the Perl-based World Wide Web Wanderer, and used it to generate an index called 'Wandex'. The purpose of the Wanderer was to measure the size of the World Wide Web, which it did until late 1993. The web's second search engine, Aliweb, appeared in November 1993. Aliweb did not use a web robot but instead depended on being notified by website administrators of the existence at each site of an index file in a particular format.

Efficient Surfing  
Relative Information  
Problems  
Mental Models  
Navigation

JumpStation (created in December 1993 by Jonathon Fletcher) used a web robot to find web pages and to build its index, and

used a web form as the interface to its query program. It was thus the first WWW resource-discovery tool to combine the three essential features of a web search engine (crawling indexing and searching .. as described below. Because of the limited resources available on the platform it ran on its indexing and hence searching were limited to the titles and headings found in the web pages the crawler encountered.

#### WHAT AND WHY ASPECT OF INFORMATION OVERLOAD WILL BE INVESTIGATED?

Web search engines work by storing information about many web pages which they retrieve from the HTML markup of the pages. These pages are retrieved by a Web crawler (sometimes also known as a spider .. – an automated Web crawler which follows every link on the site. The site owner can exclude specific pages by using robots.txt.

#### WHAT?

The search engine then analyzes the contents of each page to determine how it should be indexed (for example words can be extracted from the titles page content headings or special fields called meta tags ... Data about web pages are stored in an index database for use in later queries. A query from a user can be a single word. The index helps find information relating to the query as quickly as possible. Some search

database

engines such as Google store all or part of the source page (referred to as a cache .. as well as information about the web pages whereas others such as AltaVista store every word of every page they find. citation needed This cached page always holds the actual search text since it is the one that was actually indexed so it can be very useful when the content of the current page has been updated and the search terms are no longer in it. This problem might be considered a mild form of linkrot and Google's handling of it increases usability by satisfying user expectations that the search terms will be on the returned webpage. This satisfies the principle of least astonishment since the user normally expects that the search terms will be on the returned pages. Increased search relevance makes these cached pages very useful as they may contain data that may no longer be available elsewhere. citation needed

#### WHY?

High-level architecture of a standard Web crawler

When a user enters a query into a search engine (typically by using keywords .. the engine examines its index and provides a listing of best-matching web pages according to its criteria usually with a short summary containing the document's title and sometimes parts of the text. The index is built from the information stored with the data and the method by which the information

Problems  
Mental Models  
Navigat

is indexed. From the Google.com search engine has allowed one to search by date by clicking "Show search tools" in the leftmost column of the initial search results page and then selecting the desired date range. citation needed Most search engines support the use of the boolean operators AND OR and NOT to further specify the search query. Boolean operators are for literal searches that allow the user to refine and extend the terms of the search. The engine looks for the words or phrases exactly as entered. Some search engines provide an advanced feature called proximity search which allows users to define the distance between keywords.
